Authors’ contributions

This work was carried out in collaboration among all authors. Author TAD designed the study, performed the statistical analysis, wrote the protocol and wrote the first draft of the manuscript. Authors MU and RAD managed the analysis of the study and literature searches. All authors read and approved the final manuscript.

ABSTRACT

Aim: To evaluate the proximate composition, functional and sensory properties of a complementary food from pearl millet, soy flour and baobab fruit pulp composite flours.

Study Design: A complementary food was produced from Pearl millet, soy flour and baobab fruit pulp powder (BFP) of various proportions (10, 20, 25 and 30%). Proximate (protein, ash, moisture, fibre, fat, carbohydrate and energy value) composition, functional (Bulk density, gelation capacity, swelling index, water absorption capacity and oil absorption capacity) properties and sensory (appearance, flavour, texture and overall acceptability) attributes were determined.

Results: The results of proximate composition showed that Moisture content ranged from 10.09 – 10.98, Protein content ranged from 9.80 – 24.25, Fat content ranged from 4.94 – 16.65, Carbohydrate content ranged from 43.11 – 71.03, Fibre content ranged from 3.37 – 15.67, Ash content ranged from 2.59 – 2.87% and Energy value ranged from 367.78 – 423.69 Kcal. The functional properties showed that Water Absorption Capacity ranged from 2.70 – 2.91, Oil...
Absorption Capacity ranged from 1.90 – 2.72, Bulk Density ranged from 0.69 – 0.71, Swelling Index ranged from 0.68 – 1.04 g/ml and Gelation Capacity ranged from 5 – 10% of the complementary food samples. The sensory attribute also revealed that the complementary food samples proved to be of good quality but the controlled sample (A) was most preferred by the panellist.

**Conclusion:** It could be concluded that the Complementary food was produced from millet, baobab fruit pulp and soy flour. Though, samples were found to be low in protein, fat and energy. The carbohydrate, fibre and ash contents were found to increase with increase in baobab fruit pulp addition. Gelation capacity, swelling index and Oil absorption capacity increase with addition of baobab fruit pulp. On the other hand the bulk density and water absorption capacity decrease with increase baobab fruit pulp addition. The sensory properties indicated that sample A was the most preferred sample.

**Keywords:** Baobab Fruit Pulp (BFP); pearl millet; soybean; complementary food.

### 1. INTRODUCTION

Malnutrition is responsible, directly or indirectly, for over half of all childhood deaths. Infants and young children are at increased risk of malnutrition from six (6) months of age onwards, when breast milk alone is no longer sufficient to meet all nutritional requirements and complementary feeding needs to be started [1]. Complementary foods are often of lesser nutritional quality than breast milk. In addition, they are often given in insufficient amounts and, if given too early or too frequently, they displace breast milk. Complementary foods are food other than breast milk or infant formula such as solid, liquid and semi-solid food materials which are introduced to infants to provide nourishment [1]. Gastric capacity limits the amount of food that a young child can consume during each meal. Repeated infections reduce appetite and increase the risk of inadequate intakes. Infants and young children need a caring adult or other responsible person who not only selects and offers appropriate foods but assists and encourages them to consume these foods in sufficient quantity [2]. It is common knowledge that breast milk is the best food for infants during their first six (6) months of life. Breast milk contains all the essential nutrients and immunological factors an infant requires to maintain optimal health and growth. It also tends to protect infants against upper respiratory infection and diarrhea which are the chief causes of infant and child morbidity and mortality [3,4]. However, at an early age of six (6) months and above, the weight of the child is expected to double which breast milk alone at this point may not be sufficient for the child’s nutritional and growth needs. The adoption of recommended breast feeding and complementary feeding practice and access to the appropriate quality and amount of foods are essential component of optimal nutrition for infant and young children [1]. Several factors tend to contribute to the vulnerability of children (infants) during the complementary feeding period. These factors may include; low nutritional quality of complementary foods which most times are provided in insufficient amount to the child [5,1]. In recent years, many important advances in breast feeding promotion have been made but unfortunately the same may not be said for complementary feeding [5]. Some nutritional importance of the raw materials used: The dried baobab fruit powder contains about 12% water and various nutrients including carbohydrates, dietary fibre, B-vitamins, calcium, magnesium, potassium and iron. The fruit is 100% natural and known for its high content of vitamin C, pro-vitamin A, vitamin E, essential amino acids and calcium [4]. All of this anti oxidant is extremely important in human nutrition. Soybean also contains the followings; Protein and oil makes up about 60% of the soybean and about one third consist of carbohydrates, including polysaccharides, starchose (3.8%), raffinos (1.1%) and sucrose (5%), Phosphatides, sterols and other constituents. A variation ranging from 13.9 – 50.2% in protein has been recorded. The variation in protein and oil content in soybean is due to the locality where the beans are grown [4]. Literature reviewed that oil, sugars and other non-protein components were affected mostly by changes in the protein content. An increase in the protein content leads to a significant decrease in the non-protein constituents such as oil, sugar and pentosans. Pearl millet contains 5.8 – 20.9% protein, 63.1 – 78.5% carbohydrate, 1.4 – 2.6% soluble sugars, 1.1 – 1.8% fibre content and 4.1 – 6.4% fat content. According to research in Georgia, pearl millet is 8 – 60% higher in protein and 40% higher in lysine than is feed corn. Pearl millet is much lower in tannin than sorghum. Millet is high
– energy, nutritious food, especially recommended for children, convalescents and the elderly. Several food preparations are made from millet which differs between countries and even between different parts of a country [6]. These consist primarily of porridge or pancakes-like flat bread. However, because wholemeal quickly goes rancid, millet flour can be stored only for short periods [7]. Pearl millet is rich in B group vitamins, potassium, phosphorus, magnesium, iron, zinc, copper and manganese. It is a gluten free grain and the only grain that retain its alkaline properties after being cook which is ideal for people wheat allergies. Commercial baby food formulae are made to the highest microbiological specification and are formulated to meet the nutritional requirement of babies. They are designed to complement normal family and more appropriate than adult convenience foods. Commercial baby foods provide energy, protein, carbohydrate and fats. It also contain controlled amount of fibre, sugar and salt. Vitamins and minerals such as vitamin C and Iron are essentially added to the required amount. This research is therefore aimed at improving the quality of complementary food through the supplementation of Baobab Fruit Pulp with other cereal e.g pearl millet and Legumes such as soybean improve the nutritional quality of infant food [7].

2. MATERIALS AND METHODS

2.1 Materials

The food commodities used for this research were pearl millet (*Pennisetum glaucum*), soybean (*Glycine max.* L) and Baobab fruit pulp (*Adansonia digitata*). Soybean and pearl millet where purchased from North Bank market Makurdi, were brought to the University of Agriculture Makurdi seed research centre for identification. Baobab fruit pulp powder was obtained from Lafia Market in Nasarawa State, Nigeria.

2.2 Pearl Millet Flour Preparation

The process of flour preparation as shown in Fig. 1 consists of dry cleaning of the pearl millet i.e winnowing etc. The kernels were thereafter dehulled after mild wetting using rice dehuller. The grains were then washed and dried in a convection hot air laboratory oven (MODEL TT-9053 (Techmel and Techmel) at 50°C for 24 hrs to 14% moisture content. The dried grain was milled using a single disk attrition mill and sieved through a 455 μm screen laboratory sieve (MODEL STMN 2-CO402 JAPAN) and the under flow was used for the research [8].

2.3 Soy Flour Preparation from

The method of Filli et al. [3] was adopted as shown in Fig. 2. Soybean seeds were steeped in clean tap water at 28°C for 24 hrs in a plastic bowl. The kernel was therefore dehulled using the traditional pestle and mortar. The grains were then washed and the hulls removed. After which it was dried in a convectional laboratory hot air oven (MODEL TT-9053 (Techmel) at 50°C for 24 hrs to 14% moisture content and the mass was winnowed to remove the remaining lighter material using trail. The dehulled soybeans kernels were ground in a laboratory disc attrition mill to fine flour. The flour was sieved through a 455 μm screen laboratory sieve (MODEL STMN 2-CO402 JAPAN) and the under flow was used for further use.

![Flow chart for the production of pearl millet flour](source)

*Fig. 1. Flow chart for the production of pearl millet flour*

*Source: (Filli, 2012 [3]) with slight modification*
2.4 Baobab Fruit pulp Flour Preparation

Baobab pods were cracked using a hammer. The pulp and seeds were transferred into a ceramic mortar and it was pounded using a pestle until all the pulp was separated from the seed. The pulp was sieved through a 455 µm screen laboratory sieve MODEL STMN 2-CO402 JAPAN to remove the fibrous materials from the pulp and the underflow was used for further use as shown in Fig. 3.

3. PROXIMATE ANALYSIS

3.1 Determination of Moisture Content

Moisture content was determined by the air-oven method as described by [9]. Two grams of the sample was weighed in duplicate into Petri dishes of know weight and covered immediately. These were transferred into oven, uncovered and heated at 105°C ± 2 for 3-5 hours. The samples were then removed from the oven and placed in the desiccator to cool for 15 minutes before weighing. The process was repeated until constant weights were recorded. The loss in weight from the original weight was reported as the moisture content.

\[
\text{% Moisture Content} = \frac{W_2 - W_3}{W_2 - W_1} \times 100
\]

3.2 Determination of Crude Protein

The Kjeldahl method was used for the determination of crude protein as described by [9]. The samples (1.0 g each) were first digested in Kjeldahl digesting system. The digested samples were allowed to cool and then distilled into 2% boric acid solution containing methyl orange indicator and diluted with water after the introduction of 40% sodium hydroxide solution. The distilled samples were then titrated against 0.1 M HCl solution. A blank titration was similarly carried out and the percentage content was estimated as percentage Nitrogen × 6.25 (1 ml of 0.1M HCL ± = 0.014 g N)

\[
\text{%N} = \frac{(b-a) \times 0.1N_{\text{HCl}} \times 0.014 \times \text{dilution factor} \times 100}{\text{weight of sample}}
\]

3.3 Determination of Crude Fat Content

The Soxhlet solvent extraction method outlined in [9] was used. Two gram sample was weighed (A) into the extraction thimble and the thimble was plugged with cotton wool. It was placed back in the Soxhlet apparatus fitted with a weighed flat bottom flask (B) which was filled to about three
3.4 Determination of Crude Fibre Content

Fibre content was determined following the procedure outlined in [9] method as reported by [6]. Two grams portions of the samples were extracted using petroleum spirit (boiling point 40-60°C). This was digested in 1 liter flask using 200 ml concentrated Sulphuric acid and filtered through the California buchner system. The insoluble matter was washed with boiling water until it was free from the acid. The residue was then back into the flask with 200 ml of 0.313M NaOH. The flasks content was brought to boil for 30 minutes. The flask was allowed to stand for 1 minute and filtered immediately through a filtering cloth. The insoluble material was transferred into 100 ml beaker by means of boiling water, washed with 1% Hcl and again with boiling water to free it from acid. The insoluble material was finally washed with alcohol twice and three times with diethyl ether. The resulting residue was transferred to a dish (previously weighed) with boiling water. The dish containing the residue was dried for 2 hours, at 100°C, cooled in desiccators and weighed (W1). The dried, cooled, and weighed residue was then transferred in a muffle furnace and ignited at 600°C for 30 minutes, cooled and reweighed (W2). The percent crude fibre content was calculated as follows.

\[
\text{% Crude Fibre} = \frac{W_2 - W_3}{W_1} \times 100
\]  

Where:
W1 = weight of sample used,
W2 = weight of crucible plus sample,
W3 = weight of sample crucible + ash.

3.5 Determination of Ash

The ash content of the sample was determined by the method described by [7] a silica dish was heated to 600°C, cooled in desiccators and weighed. Then 5 g of the sample was weighed into the silica dish and transferred to the furnace. The temperature of the furnace was allowed to reach 525°C before placing the dish in it for 2 hrs. The temperature was maintained until whitish grey colour was obtained indicating that all the organic matter content of the sample had been destroyed. The dish was then brought out from the furnace and placed in the desiccators, cooled and reweighed.

\[
\text{% Ash Content} = \frac{W_2 - W_1}{\text{Weight of sample}} \times 100
\]  

Where:
W2 = weight of crucible + ash,
W1 = weight of empty crucible.

3.6 Determination of Carbohydrates

Carbohydrate was determined by difference as reported by [8].

\[
\text{% carbohydrate} = 100 - \left(\frac{\text{moisture} + \text{protein} + \text{fat} + \text{ash}}{\text{weight of sample}}\right)
\]  

4. FUNCTIONAL PROPERTIES OF SAMPLES

4.1 Determination of Gelation Capacity

The method described by [6] was used for the determination of the gelation capacity. Suspensions of the samples in 5 ml of distilled water in test tubes were prepared using 2 –20% (W/V) of the samples in test tubes. The sample test tubes were heated for 1 hour in a boiling water-bath followed by rapid cooling under running cold tap water. The test tubes were further cooled for 2 hours at 40°C. Then, the gelation capacity was determined for each sample as the least gelation concentration. That is, the concentration when the sample from the inverted test tube will not slip.

4.2 Determination of Bulk Density

The bulk density was determined as described by [6]. A 10 ml capacity graduated measuring cylinder was weighed and 50 g sample filled into it. The bottom of the flask was tapped gently on the laboratory bench several times until there
were no further diminutions of the sample level after filling to 10 ml mark.

\[
\text{Bulk Density (g/ml)} = \frac{\text{weight of sample}}{\text{volume of sample}} \tag{10}
\]

### 4.3 Determination of Swelling Index

The method of [6] was employed. One gram of the flour samples was weighed into 10ml graduated cylinder. Five (5 ml) milliters of distilled water was carefully added and the volume occupied by the sample was recorded. The sample was allowed to stand undisturbed in water for 1 hour and the volume occupies after swelling was recorded and calculated as:

\[
\text{Swelling Index} = \frac{\text{vol.occupied by sample after swelling}}{\text{vol.occupied by sample after swelling}} \tag{11}
\]

### 4.4 Determination of Water Absorption Capacity

The water absorption capacity of the flours was determine by the modified method as described by [6]. One gram of sample was mixed with 10 mL distilled water and allow to stand at ambient temperature (30 ± 2°C) for 30 min, then centrifuged for 30 min at 3,000 rpm or 2000 × g. Water absorption was examined as per cent water bound per gram flour.

### 4.5 Determination of Oil Absorption Capacity

The oil absorption capacity was also determined by the modified method as described by [6]. One gram of sample was mixed with 10 mL soybean oil (Sp. Gravity: 0.9092) and allow to stand at ambient temperature (30 ± 2°C) for 30 min, then centrifuged for 30 min at 300 rpm or 2000 × g. Oil absorption was examined as percent water bound per gram flour.

### 4.6 Energy Value

This was calculated by multiplying the values of carbohydrate, fat and protein with the Atwater Factor (4, 9, and 4) for carbohydrate, fat and protein respectively as described by [6].

### 4.7 Sensory Evaluation

Sensory evaluation based on the sensory attributes was conducted by using a standard 9-points hedonic scales method (where 1 = dislike very much and 9 = like very much) as described by [8]. A total of 30 semi-trained panelists aged 18 years and above were involved in the evaluation of appearance, flavour, texture and overall acceptability. The samples (100 g each) were coded randomly number using statistical random Tables and served to the panellists with bottled water for rinsing their mouth after every sample taste in a randomized order. The panellists were instructed to rate the attributes indicating their degree of liking or disliking by putting a number as provided on the hedonic scale according to their preference.

### 4.8 Statistical Analyses

All analyses were carried out in triplicate unless otherwise stated. Statistical significance was established using one-way analysis of variance (ANOVA), and data were reported as the mean standard deviation. Mean comparison and separation was done using Fisher’s Least Significant Difference test (LSD) at p ≤ 0.05. Statistical analysis was carried out using the SPSS 20 statistical package.

### 5. DISCUSSION

#### 5.1 Proximate Composition

The proximate composition of sample A was significantly (P<0.05) higher in protein content (24.25%), fat content (16.65%) and Energy value (423.69 Kcal) (Table 2). According to [10], the addition of soybean flour to tiger-nut in the preparation of an infant diet increases the protein, fat and energy values respectively. The Moisture content values for all the samples tend to agree with the PAG (Protein Advisory Group – United Nations) which reported moisture content of between 5-10% maximum. The range of moisture would have a positive effect on the shelf life stability of the products [11] and [10]. The Ash content of the samples ranges from 2.59 – 2.87% with the highest value in sample E (2.87%). The high Ash content of sample E could be due to the ratio of Millet Flour and Baobab Fruit Pulp Powder in the sample since both are good sources of mineral elements. Ash content of the samples was found to be less than the PAG standards which reported 10% maximum ash content. The Protein content of the samples ranges from 9.80 – 24.25% with highest value in sample A (24.25%). These values are higher compared to PAG standard (20%) respectively. This may be attributed to the protein content of soybean addition [10]. The fat content of the samples was found to range from 4.94 – 16.65% with sample A (16.65%) having the highest significance (P<0.05) value than others. This is as a result of the high soy (50%) flour content in the sample. Though, the fat contents of sample A
5.2.1 Gelation concentration (GC)

The least gelation concentration (LGC) which is defined as the lowest protein concentration at which gel remained in the inverted tube was used as index of gelation capacity. The data for LGC of different flours are given in Table 3. Composite (E) flours formed a gel at a significantly higher concentration (10 g). Sample A and B flour formed gel quickly at very lowest concentration (5 g). Wheat flours contain high protein and starch content and the gelation capacity of flours is influenced by physical competition for water between protein gelation and starch gelatinization [12]. Suresh et al. [4] reported that protein gelation was significantly affected by exposed hydrophobicity and square of sulphhydrils of proteins. As the percentage of incorporation of millet flour in wheat flour (composite flour) increased, gelling properties decreased. The low gelation concentration of A and B flour as composite flour may be added an asset for the formation of curd or as an additive to other gel forming materials in food products. The variation in the gelling properties may be ascribed to ratios of the different constituents such as protein, carbohydrates and lipids in different flours, suggesting that interaction between such components may also have a significant role in functional properties [13]. The composite flours (E) would be useful in food system such as puddings, sauce and other foods which require thickening and gelling [14].

5.2.2 Bulk density

The bulk density (g/cm³) of flour is the density measured without the influence of any compression. The bulk densities of flours ranged from 0.69 g/cc to 0.71 g/cc. The highest bulk density was observed A, B, C and D flour as shown in Table 3 and lowest was sample E (0.69 g/cc). The present study revealed that bulk density depends on the particle size and initial moisture content of flours. The obtained does not agree with those presented by [14], reported that Bulk density of composite flour increased with increase in the incorporation of different flour. However, it is clear that decreased the proportion of wheat flour increase the bulk density of composite flours. The high bulk density of flour suggests their suitability for use in food preparations. On contrast, low bulk density would be an advantage in the formulation of complementary foods [14]. Therefore, the present study suggests that high bulk density of composite flour (A, B, C and D) (Table 1) suggests its suitability to be used as thickener in food products and for use in food preparation since it help to reduce paste thickness which is an important factor in convalescent and child feeding.

5.2.3 Swelling capacity

The swelling capacity of different flours ranged between 16.00 to 22.30 ml [14]. From Table 3, it is clear that lowest value of swelling capacity was observed in A (0.68±0.13 ml) whereas the maximum in E (1.04±0.13 ml). The swelling capacity of flours depends on size of particles, types of variety and types of processing methods.
and/or unit operations. Suresh et al. [4] reported that the flour of parboiled rice has more swelling capacity as compared to raw rice. They also reported that the swelling capacity of composite flours increased with increase in the level of incorporation and decreased with level of wheat flour addition. It is explicit that the swelling capacity of composite flours is highly affected by the level of millet flour, because millet flour is rich in starch content.

5.2.4 Water absorption capacity (WAC)

The water absorption capacity for composite flours is given in Table 3. The WAC ranged between 2.70 to 2.91 for all flours. The WAC was observed highest in C (2.91) and lowest in D and E (2.70). The result suggests that addition of millet flour to wheat flour affected the amount of water absorption. This could be due to molecular structure of millet starch which inhibited water absorption, as could be seen from the lower values of WAC, with increase in proportions of other flours to wheat flours. Similar observation was reported by [12]. Suresh et al. [4] reported that lower WAC in some flours may be due to less availability of polar amino acids in flours. The increase in WAC of blends after incorporation of millet flour may be due to increase in the amylose leaching and solubility and loss of starch crystalline structure. High WAC of composite flours suggests that the flours can be used in formulation of some foods such as sausage, dough and bakery products. The increase in the WAC has always been associated with increase in the amylose leaching and solubility, and loss of starch crystalline structure. The flour with high water absorption may have more hydrophilic constituents such as polysaccharides. Protein has both hydrophilic and hydrophobic nature and therefore they can interact with water in foods. The good WAC of composite flour may prove useful in products where good viscosity is required such as soups and gravies. The observed variation in different flours may be due to different protein concentration, their degree of interaction with water and conformational characteristics [13].

5.2.5 Oil absorption capacity (OAC)

The composite flours (D and E) had highest OAC (2.72 and .44) and lowest for B (1.90). It is clear that the OAC of composite flours increased with increase in the proportion of other flours. The presence of high fat content in flours may have affected adversely the OAC of the composite flours. The OAC was found to be insignificant to each other at (p ≤ 0.05) level of significance. Therefore, the possible reason for increase in the OAC of composite flours after incorporation of millet flour is the variations in the presence of non-polar side chain, which might bind the hydrocarbon side chain of the oil among the flours. Similar findings were observed by Kaushal et al. (2012). However, the flours in the present study are potentially useful in structural interaction in food especially in flavor retention, improvement of palatability and extension of shelf life particularly in bakery or meet products where fat absorption is desired [16]. The major chemical component affecting OAC is protein which is composed of both hydrophilic and hydrophobic parts. Non-polar amino acids side chain which can form hydrophobic interaction with hydrocarbon chains of lipids [15].

5.2.6 Sensory scores

Table 4 shows the sensory scores of the samples tested. Appearance for sample A, B and C was not significant (P<0.05) difference level but was significant (P<0.05) different level from D and E. Flavour shows that there are no significant (P<0.05) difference level in all the samples tested. In terms of texture, there are no significant (P<0.05) difference level between samples A, B and C and between samples B and C and also between sample C, D and E. But there are significant (P<0.05) difference level between sample A and E, B and E and C and D. the general Acceptability indicates that there are no significant difference (P<0.05) between samples A, B, and C; samples B, C and D; samples C, D and E and between sample D and E but there are significant difference (P<0.05) between sample A and E, B and E. The sensory scores and general acceptability shows that sample A (7.66) was the most preferred amongst all the tested sample followed by sample B (7.47) and C respectively.

6. CONCLUSION

It could be concluded that the Complementary food was produced from millet, baobab fruit pulp and soy flour. Though, samples were found to be low in protein, fat and energy. The carbohydrate, fibre and ash contents were found to increase with increase in baobab fruit pulp addition. Gelation capacity, swelling index and Oil absorption capacity increase with addition of baobab fruit pulp. On the other hand the bulk density and water absorption capacity decrease with increase baobab fruit pulp addition. The sensory properties indicated that sample A was the most preferred sample.
