ABSTRACT

Introduction: *Staphylococcus aureus* is one of the main pathogens found in street food, including hot beverages. However, information about *S. aureus* isolated from street hot beverages from coffee carts is very limited in Abidjan, Côte d’Ivoire.

Aims: We aimed to characterize phenotypically *S. aureus* isolated from street hot beverages sold in Abidjan.

Methodology: A total of 400 samples of hot beverage were collected and analyzed. The identification was made through conventional microbial and biochemical analysis. Macroscopic identification on the Baird Parker agar supplement with egg yolk tellurite. Microscopic observation
1. INTRODUCTION

Street foods have easy access and generate jobs opportunities, especially for low- or uneducated people [1]. The hot drink culture is highly developed in industrialized countries and constitutes an important part of street catering. The developing country use these types of drink, but several studies have shown that manufacturers of street foods use raw materials and ingredients of poor microbiological quality and non-authorized persons are involved in this sector of activity [2,3,4]. Food safety remains a global concern despite efforts made by health and sanitation organizations [5]. Food contamination remains a real and permanent risk, especially in cities where this risk is closely linked to the consumption of ready to eat street foods [6-7]. Foodborne infections are reported worldwide, and it was estimated to be involved in more than 2 million deaths per year, mainly children [8], due solely to food and water contaminated by microorganisms. Across the world and specifically in Africa, several countries have experienced episodes of food poisoning without scientifically proved of food involvement. Several bacteria are involved in food poisoning [7,9].

Staphylococcus aureus (S. aureus) is a ubiquitous commensal bacterium on human skins and anterior nares, but frequently causes severe infections in humans [10]. S. aureus has been described as one of the most common causal agents of food poisoning associated with the consumption of raw milk cheese and is also listed as one of the pathogens likely to pose the greatest risk to human health [11-13]. The presence of this pathogen in final products is related to several factors but is usually associated with the use of contaminated raw milk and endogenous starter cultures in manufacturing the cheese, as well as with asymptomatic human carriers of S. aureus [14-15]. Another serious public health problem associated with S. aureus in food is its resistance to antimicrobials because it triggers serious infections with limited therapeutic options [16-17]. Methicillin-resistant S. aureus (MRSA) is a leading example of bacterial resistance in the world [16] and is characterized by acquisition of the mecA gene, which is located on the chromosomal cassette mec (SCCmec) [18]. For many years, MRSA staphylococcal isolates have been recognized as pathogens unique to hospitals. However, studies have documented the spread of MRSA in foods [19]. The aim of this study was to investigate the presence of S. aureus in some hot beverages (coffee, tea and cocoa) and the antimicrobial resistance profile of staphylococcal isolates from those street hot beverages collected from Abidjan, Côte d’Ivoire.

2. MATERIALS AND METHODS

2.1 Study Areas

The survey was carried out in five municipalities (Abobo, Adjamé, Yopougon, Cocody and Port-Bouët) of Abidjan to draw the characteristics of consumers of street Hot Beverages. Abidjan is located in the south of Côte d’Ivoire, and covers 57,735 ha². Abidjan had been divided into districts, arrondissements and delegations. The arrondissements corresponded to large groups, such as the Plateau, Treichville, or Adjamé, and their number increased from eight in 1967 to twelve in 1978 [20]. These districts are the basis of the delimitation of the perimeters of the ten autonomous municipalities which became the administrative units for the organization of the management of the city: Abobo, Adjamé, Attécoubé, Cocody, Koumassi, Le Plateau, Marcory, Port-Bouët, Treichville and Yopougon [21].
2.2 Survey

The survey was carried out in five municipalities (Abobo, Adjamé, Yopougon, Cocody and Port-Bouët) of Abidjan to draw the characteristics of consumers of street Hot Beverages. The criteria for including respondents were sellers and consumers who agreed to answer the questionnaires. Each consumer and seller were subjected to a series of questionnaires coupled with direct observations on hygiene. The questions relate to the behavior and preferences of the respondents as well as the health status linked to the consumption of coffee, tea and cocoa-based beverages at itinerant or fixed sellers and the consumption of these hot drinks at these sellers.

2.3 Sample Collection

Per municipalities, three kinds of hot beverages (tea, coffee, and/or cocoa) were targeted. A total of 400 samples of hot beverage made of tea (139), coffee (138), or cocoa (123) were collected in sterile tubes (Table 1). The samples were collected hot in stomacher paper and transported immediately or within 2 hours in cooler to the laboratory for microbiological analyzes.

2.4 Microbial Analysis

One (1) ml of each of the collected beverage samples was used for a decimal dilution. Each dilution (1 ml) was spread on Baird Parker agar (Biokar Diagnostics, France) supplemented with egg yolk tellurite [21] before its incubation at 37°C for 48 hours for presumptive identification of Staphylococcus sp. S. aureus referencing strain of S. aureus ATCC 25923 was used as a positive control. Macroscopic identification was made on Baird Parker agar supplemented with egg yolk tellurite. Microscopic observation was performed by Gram staining as well as biochemical tests such as catalase, DNase and coagulase and fermentation of mannitol.

2.5 Identification of Isolates by MALDI-TOF MS

After isolation, the MALDI-TOF (Bruker Daltonics™) mass spectrometry was used to confirm the Staphylococcus aureus. Samples were covered with 1.5 µl of the matrix solution (Sigma, Lyon, France). After 10 min of sonication, a centrifugation (13000 g, 5min) was performed before transferring to a clean polypropylene tube. The target plate and matrix were then dried at room temperature before identification [22]. A positive control was used (S. aureus ATCC 25923).

2.6 Antibiotic Susceptibility Testing

Antibiotic susceptibilities were determined by the disc diffusion method on Mueller-Hinton agar (Oxoid, France) according standards and recommendations of the Antibigram Committee of the French Society of Microbiology [23]. The antimicrobial tested and their concentrations on the discs of antibiotics (Bio-Rad, Marnes-LaCoquette, France) were as following: penicillin (PEN 10µg), amoxicillin (AMX 25 µg), cefoxitin (FOX 30 µg), tobramycin (TM 10 µg), gentamicin (GM 15 µg), erythromycin (ERY 15 µg), clindamycin (CMN 2 µg), levofloxacin (LVX 5 µg); norfloxacin (NOR 5 µg), ofloxacin (OFX 5 µg), vancomycin (VAN 30 µg). The reference strain Staphylococcus aureus ATCC 25923 was used as test control processed in the same conditions. Isolates were classified as susceptible or resistant to the drug.

2.7 Data Analysis

The data obtained from the survey and observations checklists were analyzed using the SPSS version 20.0 statistical software package, and then exported to Microsoft Excel for scoring. Descriptive analyses were used to summarize the variables of interest and determine relationships between them. The results were

expressed as mean ± standard deviations (±SD), frequencies, and percentages. The Chi-squared frequency test ($\chi^2$ test) was used to test the relationships between the variables. Statistically significant differences were based on 95% confidence limits.

3. RESULTS AND DISCUSSION

3.1 Results

3.1.1 Probable origin of contaminants

The probable origin of contaminants in relation to hot beverage process are compiled in Table 2. Thus, during hot beverage preparation, some contaminants occurred related to the process. Also, the highest factor risks were recorded through the treatment of products, materials or ingredients. The cooking and conservation process are also one of the determining factors linked to the beverage poisoning risks. The quality of water used to prepare and rinse recyclable cup could be a supplement contamination factor. Hot beverage contamination varied according to several factors.

3.1.2 Phenotypic characterization and species identification

All staphylococcal isolates were confirmed as gram-positive cocci, catalase positive, and coagulase and DNase positive. Presumptive staphylococcal isolates were confirmed at the species level by proteomic analysis using MALDI TOF MS, validating identification of the species as S. aureus. The contamination prevalence of the sampled hot beverage was 8.5% and vary according to the kind of beverage (Table 3) and locality of collections (Table 4). According to the kind of beverage, the highest S. aureus contamination level was recorded with tea samples (18.4%), followed by cocoa’s (8.7%) and coffee’s (1.4%).

The Table 4 indicated that the most contaminated samples by Staphylococcus aureus were collected from Yopougon (15.7%) followed by Adjame (13.7%). The least contaminated commune was Cocody (1.2%).

3.1.3 Antibiotic susceptibilities of Staphylococcus aureus isolated from street beverages

There is a variability of resistance profile of the isolated S. aureus strains (Fig. 1). All the isolated strains from street beverages were sensitive to cefoxitin and vancomycin (Fig. 1). In addition, most of S. aureus were sensitive to the aminoglycosides and quinolones tested.

3.1.4 Distribution of S. aureus Resistance according to the Beverages

According to the kind of beverage, it is observed a variability of resistance profile (Fig. 2).

3.2 Discussion

For Lieberman et al. [24], foods and beverages which are prepared and sold on places like streets, market, festival areas and consumed on the run are known as street food. Street foods especially show the eating habits of people living in big cities such as Abidjan. Survey results showed that, majority of hot street beverage vendors were foreigners (88.0%) and illiterate (71.3%). Ma et al. [25] reported that preparing and selling food on the streets provide a constant income for millions of uneducated people. Regarding the employment, street food provides a good job opportunity and income for sellers with small capitals and especially for women [26-27]. In addition, Atobla et al. [28] showed that vendors’ knowledge is poor and had lower education levels, which is also reflected in their largely inadequate facilities and unhygienic behavior while selling food.

The strains of *S. aureus* were isolated from samples of hot drinks, on all the samples analyzed, with high frequencies in tea (67.3%), cocoa (44.6%) and coffee (34.6%). Hot drinks exposed to contamination by *S. aureus* represent a significant risk for human health, in fact this pathogen is supposed to have been eliminated by heat during treatment therefore its presence in hot drinks is generally indicative of bad hygienic conditions as highlighted [29]. These results are evidence of manual contamination. The spread of *S. aureus* by hot drink handlers is a concern and should be given careful attention in the manufacturing and sales chain.

The variation in the resistance to antibiotics of strains of *Staphylococcus aureus* isolated from hot drinks based on coffee, tea and cocoa is important because strains resistant to several antibiotics have been obtained. Resistance varies depending on the antibiotic used. Note that all strains are sensitive to levofloxacin, norfloxacin, ofloxacin, ceftriaxone and vancomycin. These results have also been reported by Attien et al. [17]. In addition, certain antibiotics which were initially sensitive have increasingly become resistant. Variable resistance was observed depending on the origin of the strains to antibiotics such as penicillin and erythromycin, amoxicillin and gentamicin. This trend was obtained by Resch et al. [30], who showed that strains of coagulase staphylococci isolated from food had resistance to oxacillin. This is reported by Magiorakos et al. [31] who stated that today almost all strains of *S. aureus* have acquired resistance to penicillin. These results could be an indicator of a prophylactic route for the treatment of *S. aureus* infections. Penicillin was the first antibiotic discovered in 1929 by Alexander Fleming, *S. aureus* were sensitive at this time. Resistance to oxacillin indicates the presence of methicillin-resistant strains among the strains isolated. This would increase the risk of infection in the event of contamination by *S. aureus* methi- resistant which is very difficult to manage. However, additional tests are required to clarify the presence of this type of strain.

4. CONCLUSION

It is observed that street vendors preferred drinking coffee to boost of energy to sell. According to them, tea was the most beverages consumed by Ivorians. The results from this street vendors showed that most street vendors are foreigners and illiterate. These street vendors therefore need training in basic hygiene practice to avoid risks such as food contamination or throwing plastic cups on the street. In addition, several bacteria were isolated; highlighting the potential risk incurred by compomers. The isolated bacteria are mostly multiresistant to conventional molecule antibiotics.

DISCLAIMER

The products used for this research are commonly and predominantly use products in our area of research and country. There is absolutely no conflict of interest between the authors and producers of the products because we do not intend to use these products as an avenue for any litigation but for the advancement of knowledge. Also, the research was not funded by the producing company rather it was funded by personal efforts of the authors.

CONSENT

As per international standard or university standard, respondents’ written consent has been collected and preserved by the author(s).

ACKNOWLEDGEMENTS

The authors thank street beverage vendors. This work was supported by ASCAD (Academy of Sciences, Arts, Cultures of Africa and African Diasporas) funds.
