Original Research Article

ABSTRACT

Peda, a heat desiccated traditional dairy product popular in northern India suffers from poor shelf life due loss of moisture from the surface, mold growth, rancidity etc. Packaging plays an important role in controlling microbial growth as well as biochemical changes and the shelf life can be increased by changing the packaging system. In the present study the role of packaging materials on the storage stability of peda was evaluated at ambient (30±1⁰C) and refrigerated (7±1⁰C) conditions. Peda was prepared in the laboratory from standardized cow milk (4.5% fat and 8.5% SNF) with addition of 8% sugar on the basis of milk and kept without packaging (P₀) as well as packaged in two most suitable packaging materials viz. paper box (P₁) and polypropylene pouches (P₂). During storage the sensory quality, physico-chemical properties, texture profile and microbiological quality was carried out at regular interval. It was found that the rate of most of the quality deteriorative parameters was rapid in P₀ followed by P₁ and P₂ at both storage temperatures. Based on the results obtained in this study it can be concluded that at ambient temperature peda samples could be best preserved up to 4 days without packaging, 8 days in paper box and 14 days in polypropylene pouches whereas refrigerated samples kept well up to 20, 30 and 50 days in P₀, P₁ and P₂ respectively.

Keywords: Biochemical changes; storage stability; polypropylene; paper box; texture profile.
1. INTRODUCTION

As per the statistics of the Department of Animal Husbandry, Ministry of Agriculture, India is the largest milk producing country in the World with 176.35 million tonnes milk production during the year 2017-18 of which 50 – 55% is converted into various traditional milk products [1-4]. The indigenous milk products are developed at household and farm levels to preserve surplus milk using some traditional techniques. These traditional dairy products have commercial importance as they account for over 90% of all the milk products consumed in the country [5].

Milk based sweet delicacies are an integral part of social, religious and cultural heritage in Indian society and have great social, economic significance [6]. Pedas are mostly consumed in India as religious ‘prasad’ in temples. Khoa, prepared by heat desiccation of whole milk in an open iron pan into a thick concentrated mass, is used as base material for manufacturing of peda [7]. It is made by admixture of khoa with 30 – 35% sugar, with or without addition of natural or artificial colour and flavour and heated until the desired characteristic texture, brown colour and caramelized flavour develops [8]. The physico-chemical, rheological and sensory properties of peda depend on the manufacturing techniques, type and quality of raw materials used, additives, individual skills, trade practices and consumers choices. However, being prepared at small scale in unorganized sectors, proper hygienic conditions are not maintained and thus inferior quality product is often marketed [9].

Milk based sweets undergo several physical, biochemical and microbiological changes during storage making them unfit for human consumption and reducing their market value [10]. Peda is expected to have good shelf life due to combined effect of low moisture and high sugar percentage which are sufficient to prevent microbial growth [11]. However, improper handling and packaging result in limited shelf life of this popular sweetmeat through loss of moisture, development of rancidity and surface mold growth during storage making it unfit for consumption [11,12]. Because of its intermediate moisture range and non-acidic nature bacterial growth is not common in peda and the spoilage occurs mainly due to growth of surface yeasts and molds. Packaging plays an important role in both handling and storage of peda and the shelf life can be increased by changing the packaging system. Varieties of packaging material had been used by early researchers for packaging of peda. Some researchers packed peda in three types of polythene bags viz. low density transparent, medium density blue and low density opaque polythene pouches. Packaging of peda in 100 and 300 gauge low density polyethylene pouches followed by heat sealing was done by [13]. Peda can be packed in paper boards/ boxes having a parchment paper liner or grease proof paper liner [14], in multilayer transparent laminates with oxygen scavenger [15], in low density polyethylene (LDPE) materials [16,17]. Many researchers worked on modified atmosphere packaging (MAP) of khoa based sweets for extension of shelf life [2,9,18,19,20]. However, the high cost of MAP may restrict its application in these popular traditional sweetmeats which are still dominated by unorganized sectors.

Therefore, with a view to determine the shelf life of peda prepared in laboratory and packaged in various packaging materials for characterizing this traditional sweetmeat of India as well as generating valuable database on the basis of their sensory, chemical and microbiological changes during storage the present work has been under taken.

2. MATERIALS AND METHODS

The study was carried out in the laboratory of Department of Dairy Chemistry, Faculty of Dairy Technology, West Bengal University of Animal & Fishery Sciences, Kolkata, India.

2.1 Raw Materials

Standardized cow milk (4.5% fat and 8.5% SNF) and sugar used for manufacturing of peda were procured from the local market. Paper board boxes and polypropylene pouches for packaging of peda were purchased from market of Kolkata, India. All the chemicals used were of analytical grade and purchased from HIMEDIA®.

2.2 Preparation of peda

In the laboratory peda was manufactured following the standard method [21]. Standardized cow milk was concentrated in open pan with continuous stirring. When heat coagulation of milk solids started sugar (8% of milk) was added and heated for desiccation with continuous stirring till the product attained characteristic colour and texture. Peda was cooled to room temperature, shaped and packaged in paper board boxes and polypropylene pouches of dimensions 17 cm × 15 cm × 0.022 cm.
2.3 Storage Stability of peda

The peda samples were analyzed every alternate day during ambient storage (30±1°C) and at 5 days interval during refrigerated storage (7±1°C) for sensory, physico-chemical textural and microbiological changes.

2.3.1 Changes in sensory attributes

The sensory quality of peda was analyzed on the basis of colour, flavour, body & texture and overall acceptability throughout the storage by a semi-trained panel of judges consisting of seven members by using a nine point hedonic scale [22].

2.3.2 Changes in physico-chemical parameters

The changes in moisture content during storage were determined by oven drying method [23]. The titratable acidity was measured in terms of percent lactic acid [24] and the free fatty acid (FFA) content in terms of percent oleic acid [25]. The extent of lipid oxidation was measured in terms of peroxide value and determined by iodometric titration method [26]. The changes in hydroxyl methyl furfural (HMF) content in peda during storage indicated the degree of Maillard browning reaction and was determined using Spectrophotometer [27]. Tyrosine value was measured to determine the extent of protein degradation [28].

2.3.3 Changes in texture profile

A Texture Analyzer (Model: TAHDi, Stable Micro System, UK) fitted with a 250 kg load cell was used for two bites linear compression of peda samples. A cross pretest speed of 2 mm/s, test speed of 5 mm/s, post-test speed of 5 mm/s and interval of 5 s between two successive bites were employed for 50% compression of the samples. A cylindrical probe of 75 mm diameter was used for textural study. The texture analyzer having separate software (Texture Expert) for its operation was run under Windows environment to get the Texture Profile Analysis (TPA) data from the measurements. The hardness, fracturability and adhesiveness were directly calculated from Force—Time curve while other parameters like springiness, cohesiveness, gumminess and chewiness were obtained directly from the Microprocessor.

2.3.4 Changes in microbiological quality

Microbiological analysis of peda samples was examined on initial and final days during storage for total viable count as well as yeast and mould counts as per the standard methods [29]. The data on microbiological quality is presented in log₁₀ values.

3. RESULTS AND DISCUSSIONS

For any dairy product, the physico-chemical behavior during storage is one of the prime interests of the producers and the consumers since it leads towards the termination of the shelf life of the product. In the present study two types of most suitable package viz. paper box and polypropylene pouches were used for packaging of peda to observe their effectiveness. It was noted that peda samples kept under ambient temperature (30±1°C) were acceptable up to 4 days without packaging (P₀), 8 days in paper box (P₁) and 14 days in polypropylene pouches (P₂) whereas refrigerated samples (stored at 7±1°C) kept well up to 20, 30 and 50 days in P₀, P₁ and P₂ respectively.

3.1 Changes in Sensory Properties During Storage

The changes in sensory profile of peda during storage at 30±1°C and 7±1°C were represented in graph 1(a-d) and 2(a-d) respectively. From these figures it was clear that irrespective of packaging materials all samples showed a decreasing trend in sensory scores viz. flavour, body and texture, colour and appearance and overall acceptability during storage. The changes were faster in ambient temperature as compared to refrigerated storage and more prominent during the later stage of storage. It was also found that the product degrade rapidly when stored unpackaged followed by paper box and polypropylene pouches. The decrease in the scores caused due to loss of freshness, loss of moisture, releasing of free fat on the product surface and changes in various physico-chemical parameters during storage.

Fig. 2. Changes in sensory profile of *peda* during storage at 7±1°C
3.2 Changes in Physico-chemical Properties during Storage

Graph 3(a-f) and 4(a-f) illustrated the changes in physico-chemical properties of peda samples under various packaging conditions during storage at 30±1°C and 7±1°C respectively. Moisture content had profound role on acceptability of the product during storage as far as browning reaction, release of free fatty acids, protein degradation and other biochemical changes are concerned. The moisture content decreases from an initial value of 19.37% during storage which was rapid in the product without packaging at 30±1°C [Graph 3(a)]. Earlier researchers had also reported considerable loss of moisture during storage making the product dry, hard and unacceptable on sensory evaluation [14,16]. Due to conversion of lactose into lactic acid by the microorganisms the titratable acidity of peda samples rapidly increased during storage which attained a maximum value of 0.88% from an initial lactic acid content of 0.58% on 50th day of storage at 7±1°C and packaged in P2 [Graph 4(b)]. The lipid breakdown was represented in terms of free fatty acids and peroxide value which reached to maximum value of 0.112 from 0.063% of oleic acid [Graph 4(c)] and 1.98 from 1.12 m. eq. of O2 per kg samples [Graph 4(d)] respectively in P2 stored under refrigeration. The free fat released during preparation of peda and high moisture content of the product could be responsible for lipolysis during storage [19]. Free fat present in peda is also susceptible to oxidation leading to the increase in peroxide value and development of off-flavour. The protein degradation and browning index were reported as tyrosine value (mg/ 100 gm) [Graph 3(e) and 4(e)] and HMF (micromoles/ 100 gm) [Graph 3(f) and 4(f)] respectively which also showed similar trends during storage. The -SH groups were converted to S-S group in presence of oxygen leading to increase in browning and HMF value during storage.

3.3 Changes in Texture Profile during Storage

Texture is the attribute which determine ultimate acceptance of the product by consumers. Table 1 showed the texture profile of peda samples stored under various conditions. In the table texture profile was represented initially and the day up to which the product was acceptable on the basis of sensory quality. The table clearly depicted significant increase in all the textural parameters of peda samples except springiness and cohesiveness which showed decreasing trend during storage under various conditions. Increase in hardness was responsible for lowering of body and texture score of the samples during storage. The hardness was increased from an initial value of 55.247 to 250.63 kg in P2 after 50 days of storage at 7±1°C. The fracturability value was increased to 0.086 from 0.037 kg in P0 at 30±1°C. The springiness value decreased from 0.368 to 0.257, 0.239 and 0.225 mm in P0, P1 and P2 respectively during storage at 30±1°C whereas at 7±1°C the values were 0.213, 0.195 and 0.181 mm respectively in P0, P1 and P2 at the end of storage period. For cohesiveness highest decrease was 0.0227 – 0.139 mm in P0 at 30±1°C after 4 days of storage. The gumminess was increased from 11.244 to 21.273 kg in P2 at 7±1°C after 50 days of storage and chewiness from 0.003 to 0.014 kg-mm in P0 at 7±1°C after 20 days of storage. Almost similar observations were reported by other researchers [8,16,19,30].

3.4 Changes in Microbial Quality during Storage

The initial and final microbial count of peda samples packaged in different packaging materials during storage was represented in table 2. The average initial total bacterial count (log10 cfu/ gm) in the peda samples was found to be 5.28 which were increased to 7.11, 6.75 and 6.83 in P0, P1 and P2 after 4, 8 and 14 days of storage at 30±1°C respectively. A similar trend in increase in total bacterial count was also noticed during storage of peda samples at 7±1°C. Yeast and mold counts were also increased significantly during storage under various packaging conditions and temperature and the highest increase was noticed in the product without packaging and stored at7±1°C where the count was reported as 3.04 log10 cfu/ gm. Earlier workers also reported increase in microbial counts during storage of various khoa based sweets [2,10,31]. From the trend of increase in microbial count it was clear that packaging materials offered some protection towards the growth of microorganisms by preventing ingress of moisture, light and air.

4. CONCLUSION
With a view to improve the shelf life of peda, a popular Indian traditional sweet delicacy, the present study was undertaken where the storage stability of peda prepared in the laboratory from standardized cow milk was determined by packaging interventions. From the results of sensory, physico-chemical textural and microbial properties the shelf life of the product was found to differ considerably with different packaging techniques. During storage in all samples there was gradual decrease in the sensory parameter making the product unfit for consumption. Among physico-chemical parameters the moisture content decreased significantly whereas titratable acidity, free fatty acids, peroxide value, tyrosine value and HMF content gradually increased during storage as a result of lactose, lipid and protein breakdown. In the texture profile analysis it was found that all the textural parameters increased significantly throughout storage. The microbial counts were also rapidly increased in all samples during storage and the growth of yeast and molds was the major factor limiting the shelf life. It was noticed that the changes were rapid at ambient condition (30±1°C) than refrigerated storage (7±1°C) and the product degraded rapidly without packaging followed by paper box and polypropylene pouches respectively. From the results it can be concluded that peda samples were kept well up to 4 days without packaging (P0), 8 days in paper box (P1) and 14 days in polypropylene pouches (P2) stored at 30±1°C whereas refrigerated samples were acceptable up to 20, 30 and 50 days in P0, P1 and P2 respectively. The study was useful as it will provide sufficient data for characterization as well as shelf life enhancement of this popular Indian sweetmeat and will help to undertake newer studies pertaining to improving the shelf life of various indigenous dairy products of India.
